#### **Activity 5: Consolidating Playbook plays**

## 1. Objectives:

- 1.1 Use when command in playbook for different OS distributions
- 1.2 Apply refactoring techniques in cleaning up the playbook codes

#### 2. Discussion:

We are going to look at a way that we can differentiate a playbook by a host in terms of which distribution the host is running. It's very common in most Linux shops to run multiple distributions, for example, Ubuntu shop or Debian shop and you need a different distribution for a one off-case or perhaps you want to run plays only on certain distributions.

It is a best practice in ansible when you are working in a collaborative environment to use the command git pull. git pull is a Git command used to update the local version of a repository from a remote. By default, git pull does two things. Updates the current local working branch (currently checked out branch) and updates the remote-tracking branches for all other branches. git pull essentially pulls down any changes that may have happened since the last time you worked on the repository.

#### Requirement:

In this activity, you will need to create a CentOS VM. Likewise, you need to activate the second adapter to a host-only adapter after the installations. Take note of the IP address of the CentOS VM. Make sure to use the command *ssh-copy-id* to copy the public key to CentOS. Verify if you can successfully SSH to CentOS VM.

## Task 1: Use when command for different distributions

1. In the local machine, make sure you are in the local repository directory (*CPE232\_yourname*). Issue the command git pull. When prompted, enter the correct passphrase or password. Describe what happened when you issue this command. Did something happen? Why?

## only in your repository run the ansible command.

2. Edit the inventory file and add the IP address of the Centos VM. Issue the command we used to execute the playbook (the one we used in the last

activity): ansible-playbook --ask-become-pass install\_apache.yml. After executing this command, you may notice that it did not become successful in the Centos VM. You can see that the Centos VM has failed=1. Only the two remote servers have been changed. The reason is that Centos VM does not support "apt" as the package manager. The default package manager for Centos is "yum."

3. Edit the *install\_apache.yml* file and insert the lines shown below.

```
    hosts: all become: true tasks:

            name: update repository index apt: update_cache: yes when: ansible_distribution == "Ubuntu"
            name: install apache2 package apt: name: apache2 when: ansible_distribution == "Ubuntu"
            name: add PHP support for apache apt: name: libapache2-mod-php when: ansible_distribution == "Ubuntu"
```

Make sure to save the file and exit.

```
skipping: [192.168.56.102]
changed: [192.168.56.104]
TASK [add PHP support for apache] *******************************
skipping: [192.168.56.102]
changed=0
                                      unreachable=0
                                                    failed=0
skipped=3 rescued=0 ignored=0
                    : ok=0
                            changed=0
                                                    failed=0
skipped=0
         rescued=0
                   ignored=0
                                      unreachable=0
                                                    failed=0
         rescued=0
                    ignored=0
skipped=0
bencito@bencito-VirtualBox:~/CPE232_Bencito$
```

If you have a mix of Debian and Ubuntu servers, you can change the configuration of your playbook like this.

The cent os was skip because it is not called in the repository you need to edit it and called the cent os.

name: update repository index
 apt:
 update\_cache: yes
 when: ansible\_distribution in ["Debian", "Ubuntu]

*Note*: This will work also if you try. Notice the changes are highlighted.

**4.** Edit the *install\_apache.yml* file and insert the lines shown below.

```
hosts: all
become: true
tasks:

    name: update repository index

  apt:
    update_cache: yes
  when: ansible_distribution == "Ubuntu"
- name: install apache2 package
  apt:
    name: apache2
    stae: latest
  when: ansible_distribution == "Ubuntu"

    name: add PHP support for apache

  apt:
    name: libapache2-mod-php
    state: latest
  when: ansible_distribution == "Ubuntu"

    name: update repository index

  dnf:
    update_cache: yes
  when: ansible_distribution == "CentOS"
- name: install apache2 package
  dnf:
    name: httpd
    state: latest
  when: ansible_distribution == "CentOS"

    name: add PHP support for apache

  dnf:
    name: php
    state: latest
  when: ansible_distribution == "CentOS"
```

Make sure to save and exit.

```
install_apache.yml *
- name: add php support for apache
    name: libapache2-mod-php
    state: latest
 when: ansible_distribution == "Ubuntu"
- name: update repository index
  dnf:
    update_cache: yes
  when: ansible_distribution == "CentOS"
- name: install httpd package
 dnf:
    name: httpd
    state: latest
  when: ansible distribution == "CentOS"
- name: add php support for apache
  dnf:
    name: php
    state: latest
  when: ansible_distribution == "CentOS"
                           ^W Where Is
                                           ^K Cut
            ^O Write Out
                                                          ^T Execute
Help
Exit
               Read File
                              Replace
                                             Paste
                                                             Justify
```

# Now, the cent os was read because I added it on my nano script and into my repository.

```
bencito@bencito-VirtualBox: ~/CPE232_Bencito
skipping: [192.168.56.102]
changed: [192.168.56.102]
unreachable=0
                                   failed=0
skipped=3 rescued=0 ignored=0
192.168.56.103 : ok=0
             : ok=0
                                  failed=0
                   changed=0
      rescued=0 ignored=0
skipped=0
                                   failed=0
                          unreachable=0
skipped=3 rescued=0 ignored=0
bencito@bencito-VirtualBox:~/CPE232_Bencito$
```

- 5. To verify the installations, go to CentOS VM and type its IP address on the browser. Was it successful? The answer is no. It's because the httpd service or the Apache HTTP server in CentOS is not yet active. Thus, you need to activate it first.
  - 5.1 To activate, go to the CentOS VM terminal and enter the following: systemctl status httpd

The result of this command tells you that the service is inactive.

```
[bencito@localhost ~]$ systemctl status httpd
  httpd.service - The Apache HTTP Server
  Loaded: loaded (/usr/lib/systemd/system/httpd.service; disabled; vendor preset: disabled)
  Active: inactive (dead)
   Docs: man:httpd(8)
        man:apachectl(8)
[bencito@localhost ~]$ ■
```

5.2 Issue the following command to start the service:

sudo systemctl start httpd

(When prompted, enter the sudo password)

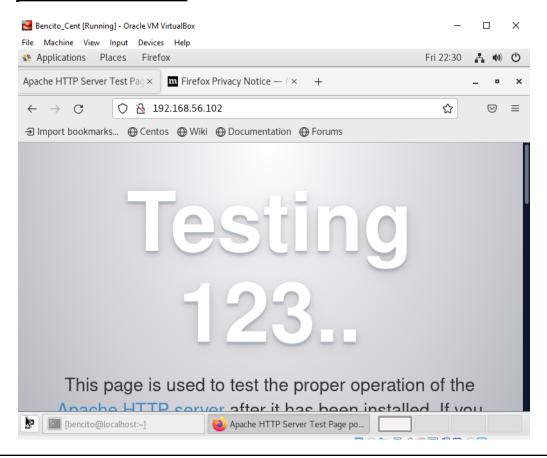

sudo firewall-cmd --add-port=80/tcp

(The result should be a success)

```
[bencito@localhost ~]$ sudo systemctl start httpd
[sudo] password for bencito:
[bencito@localhost ~]$ sudo firewall-cmd -add-port=80/tcp
usage: see firewall-cmd man page
firewall-cmd: error: unrecognized arguments: -add-port=80/tcp
[bencito@localhost ~]$ sudo firewall-cmd --add-port=80/tcp
success
[bencito@localhost ~]$
```

5.3 To verify the service is already running, go to CentOS VM and type its IP address on the browser. Was it successful? (Screenshot the browser)

#### yes, it was successful.

## Task 2: Refactoring playbook

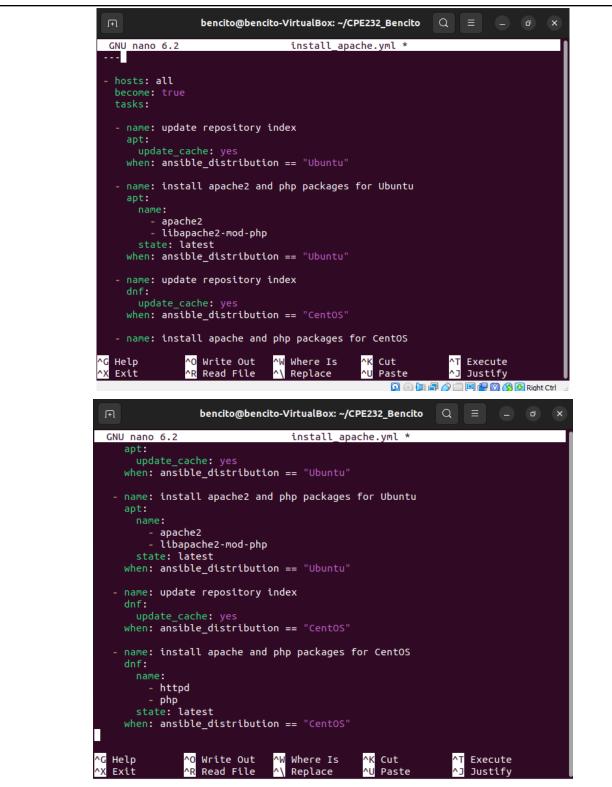

This time, we want to make sure that our playbook is efficient and that the codes are easier to read. This will also makes run ansible more quickly if it has to execute fewer tasks to do the same thing.

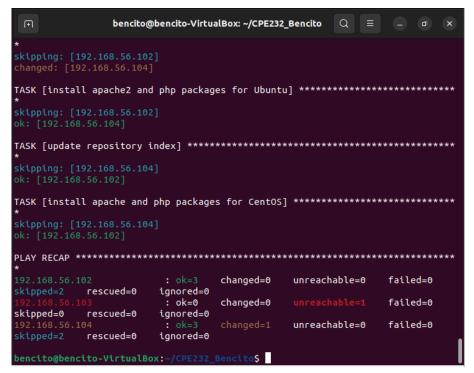

1. Edit the playbook *install\_apache.yml*. Currently, we have three tasks targeting our Ubuntu machines and 3 tasks targeting our CentOS machine. Right now, we try to consolidate some tasks that are typically the same. For example, we

can consolidate two plays that install packages. We can do that by creating a list of installation packages as shown below:

```
hosts: all
become: true
tasks:
- name: update repository index Ubuntu
  apt:
    update_cache: yes
  when: ansible_distribution == "Ubuntu"
- name: install apache2 and php packages for Ubuntu
  apt:
    name:
      - apache2
      - libapache2-mod-php
    state: latest
  when: ansible_distribution == "Ubuntu"
- name: update repository index for CentOS
  dnf:
    update_cache: yes
  when: ansible_distribution == "CentOS"
- name: install apache and php packages for CentOS
  dnf:
    name:
      - httpd
      - php
    state: latest
  when: ansible_distribution == "CentOS"
```

Make sure to save the file and exit.

2. Edit the playbook *install\_apache.yml* again. In task 2.1, we consolidated the plays into one play. This time we can actually consolidated everything in just 2 plays. This can be done by removing the update repository play and putting the

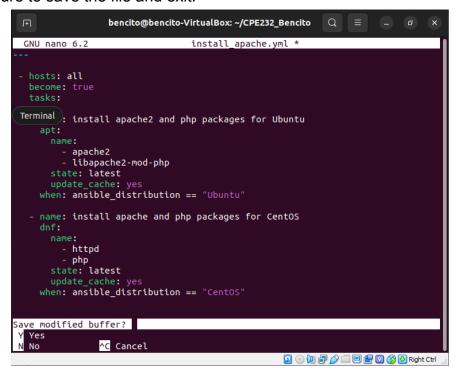

command *update\_cache: yes* below the command *state: latest*. See below for reference:

```
hosts: all
become: true
tasks:
 - name: install apache2 and php packages for Ubuntu
   apt:
    name:
      - apache2
      - libapache2-mod-php
   state: latest
    update_cache: yes
  when: ansible_distribution == "Ubuntu"
 - name: install apache and php packages for CentOS
   dnf:
     name:

    httpd

       - php
    state: latest
   when: ansible_distribution == "CentOS"
```

Make sure to save the file and exit.

```
bencito@bencito-VirtualBox: ~/CPE232_Bencito □ □
                           changed=0
                                    unreachable=0
                                                 failed=0
        rescued=0
                  ignored=0
                                                 failed=0
                   : ok=0
                           changed=0
skipped=0
         rescued=0
                  ignored=0
                                    unreachable=0
                                                 failed=0
         rescued=0
                 ignored=0
bencito@bencito-VirtualBox:~/CPE232_Bencito$ nano install_apache.yml
bencito@bencito-VirtualBox:~/CPE232_Bencito$ ansible-playbook --ask-become-pass
install_apache.yml
BECOME password:
TASK [install apache2 and php packages for Ubuntu] **********************
```

```
TASK [install apache2 and php packages for Ubuntu] ***********************
TASK [install apache and php packages for CentOS] ***********************
skipping: [192.168.56.104]
ok: [192.168.56.102]
changed=0
                                    unreachable=0
                                                 failed=0
skipped=1 rescued=0 ignored=0
192.168.56.103 : ok=0
                          changed=0
                                                 failed=0
skipped=0
        rescued=0
                  ignored=0
                                    unreachable=0
                                                 failed=0
                          changed=0
skipped=1 rescued=0
                  ignored=0
bencito@bencito-VirtualBox:~/CPE232_Bencito$
```

# The result is still the same nothing changed.

3. Finally, we can consolidate these 2 plays in just 1 play. This can be done by declaring variables that will represent the packages that we want to install.

Basically, the apache\_package and php\_package are variables. The names are arbitrary, which means we can choose different names. We also take out the line when: ansible\_distribution. Edit the playbook <code>install\_apache.yml</code> again and make sure to follow the below image. Make sure to save the file and exit.

```
---
- hosts: all
become: true
tasks:
- name: install apache and php
apt:
    name:
    - "{{ apache_package }}"
    - "{{ php_package }}"
    state: latest
    update_cache: yes
```

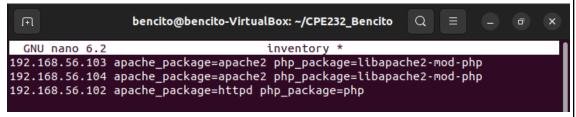

```
TASK [install apache and php] *******************************
[WARNING]: Updating cache and auto-installing missing dependency: python-apt
ok: [192.168.56.104]
changed=0
                                 unreachable=0
skipped=0
       rescued=0 ignored=0
                 : ok=0
                        changed=0
                                            failed=0
       rescued=0 ignored=0
skipped=0
                                            failed=0
                        changed=0
                                 unreachable=0
skipped=0 rescued=0 ignored=0
bencito@bencito-VirtualBox:~/CPE232_Bencito$
```

# The result was not successful. because I need to change the inventory first and the cent os was not read.

4. Unfortunately, task 2.3 was not successful. It's because we need to change something in the inventory file so that the variables we declared will be in place. Edit the *inventory* file and follow the below configuration:

```
192.168.56.120 apache_package=apache2 php_package=libapache2-mod-php
192.168.56.121 apache_package=apache2 php_package=libapache2-mod-php
192.168.56.122 apache_package=httpd php_package=php
```

Make sure to save the *inventory* file and exit.

**Finally**, we still have one more thing to change in our *install\_apache.yml* file. In task 2.3, you may notice that the package is assign as apt, which will not run in CentOS. Replace the *apt* with *package*. Package is a module in ansible that is generic, which is going to use whatever package manager the underlying host or the target server uses. For Ubuntu it will automatically use *apt*, and for

CentOS it will automatically use *dnf*. Make sure to save the file and exit. For more details about the ansible package, you may refer to this documentation:

<u>ansible.builtin.package – Generic OS package manager — Ansible Documentation</u>

Run *ansible-playbook --ask-become-pass install\_apache.yml* and describe the result.

```
BECOME password:
changed=0
                    unreachable=0
                           failed=0
skipped=0 rescued=0 ignored=0
          : ok=0
               changed=0
                           failed=0
skipped=0 rescued=0
          ignored=0
               changed=0
                    unreachable=0
                           failed=0
skipped=0 rescued=0
          ignored=0
bencito@bencito-VirtualBox:~/CPE232_Bencito$
```

It was successful, because I changed the dnf and apt into package to read the centOS.

# **Supplementary Activity:**

1. Create a playbook that could do the previous tasks in Red Hat OS.

#### Reflections:

Answer the following:

1. Why do you think refactoring of playbook codes is important?

It is important. because when you refactor the playbook. It will allow you to write programs faster. Ultimately, it all comes down to one thing: refactoring helps speed up the development of a code and to read those servers that you added.

2. When do we use the "when" command in playbook?

We use the "when" command when you run the task on all hosts. For example, when all the server was on the firewall it would run the given package on that server.
